Introduction

Banana bunchy top disease (BBTD), caused by the bunchy top virus (BBTV), is spread by the banana aphid and by planting infected planting material. Present in 14 countries in Sub-Saharan Africa, it causes accelerating production losses and reduced access to clean seed. Although yield decline is more rapid in some cultivars, none are resistant.

Recovery of banana production in nine BBTD-affected pilot sites was undertaken in a research project through the CGIAR Consortium Research Program: Roots, Tubers and Bananas (RTB).

Hypothesis: Using existing knowledge and technologies, with virus indexing, preferred banana diversity, while linking formal and informal seed systems can achieve sustainable banana production in BBTD affected areas.

Seed system capacity at pilot sites

Fig. 1. The clean seed supply options at pilot sites. Relative to present planting activities at the beginning of the project, green circles represent capacity developed during the project implementation. Size is a relative measure of importance.

Fig. 2. Propagation of bananas at pilot sites: Tissue culture propagation (left), micropropagation (middle), split corns approach (top right), suckers (bottom left), and farmer-to-farmer seed sharing among farmers.

Acknowledgement: This work is funded through the CGIAR programme on Root, Tubers and Bananas (RTB).

Prepared for the ISAG meeting, 10th - 12th October 2016, Montpellier, France

Lessons

- Planting material for replanting BBTD infected areas depends on clean source material; diverse multiplication approaches. Risk analysis and virus indexing are also needed to plan the movement of planting material: Lab - Nursery - Field.
- A local seed system renewed for BBTD control should incorporate local varieties and preferences and link with regional and national germplasm collections to reduce farm household temptation to introduce unwanted material.
- Clear gap between local materials and farmer demands (e.g. US\$ 1.5) can be bridged with community seed gardens and local seed exchanges if virus monitoring standards are followed.

BBTD control and banana diversity at pilot sites

Fig. 3. Doubling existing cultivars preferred for many reasons. Blue: In recovery efforts to distribute only market oriented or available cultivars. Orange: create a potential avenue of infection as farmers obtain planting materials from doubtful sources for preferred cultivars.

Role of informal seed systems

Fig. 4. Source of planting material in three pilot sites showing the predominance of local sources of suckers. Farmers directly responsible for sucker upgrading must recognize BBTD symptoms, but alternative sources of low risk planting material are also needed.

Linking formal and informal seed systems

Fig. 5. A potential seed system linking informal and formal systems to address BBTD: maintaining clean fields facilitates the production of local seed and a cleaner informal seed exchange system, combining directly with virus indexing if necessary.
